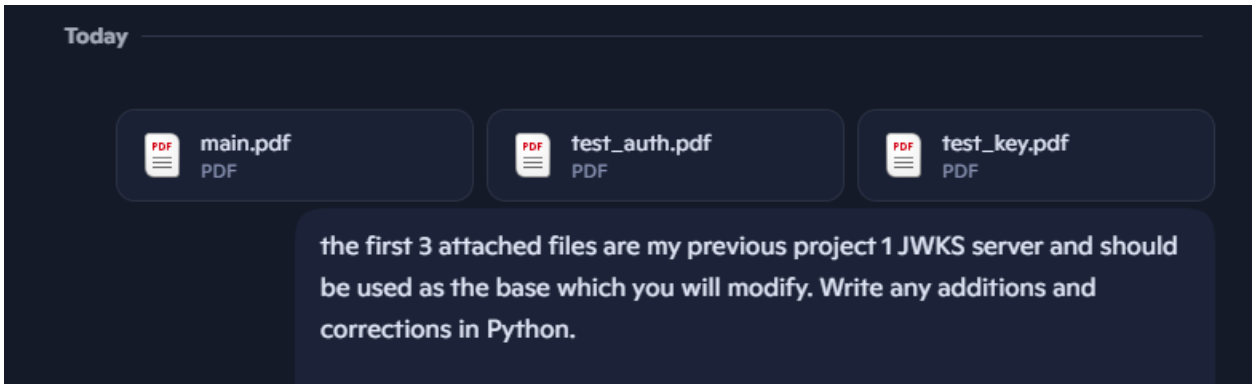
AI Usage Statement

This is the document containing all the prompts and responses I used to generate this code. I used Copilot to generate everything. The following is the prompts and responses from Copilot.

Prompt 1:

[the original codes from project 1 were uploaded here as PDFs (see screenshot)]



the first 3 attached files are my previous project 1 JWKS server and should be used as the base which you will modify. Write any additions and corrections in Python.

Extending the basic JWKS server Objective In the realm of cybersecurity, SQL injection stands out as a notorious threat capable of exposing and compromising sensitive data. This project aims to fortify your JWKS server, a key component in modern authentication systems, against such vulnerabilities by using a database to store the private keys. By using a database, our private keys can be persisted to disk, ensuing availability in the event the server is restarted (or even moved). While this project does not receive direct user input, care should still be taken with SQL queries to avoid injection attacks.

This project uses SQLiteLinks to an external site., a single-file database, to enhance your JWKS server. SQLite is not a database server, but a serverless database that relies on drivers/libraries in your program to create, read, update, and delete database rows. To utilize SQLite, you'll be modifying your previous project to:

Create/open a SQLite DB file at start. Write your private keys to that file. Modify the POST:/auth and GET:/.well-known/jwks.json endpoints to use the database. By integrating SQLite and emphasizing secure database interactions, this project not only enhances our server's

functionality but crucially focuses on preventing malicious SQL query manipulation, ensuring our authentication processes remain resilient and trustworthy.

Background SQLite installationLinks to an external site. Familiarize yourself with the DB drivers for your language. Database query parametersLinks to an external site. Familiarize yourself with how SQLite uses query parameters to avoid SQL injection. To ensure you can complete Project 2, the base files for Project 1 are available Download Project 1 are available. Zip password: d715df26-a7c3-441a-bc95-42c8d18da8a8

Requirements SQLite backed storage File name: totally_not_my_privateKeys.db Table schema: CREATE TABLE IF NOT EXISTS keys(kid INTEGER PRIMARY KEY AUTOINCREMENT, key BLOB NOT NULL, exp INTEGER NOT NULL) Save private keys to the DB Private keys can be generated and saved either on program start or before a JWT is signed. To ensure POST:/auth can be tested: Generate/store at least one key that expires now (or less) and one key that expires in 1 hour (or more). HINT: SQLite doesn't have very many datatypes it can work with, and "RSA Private Key" definitely isn't one of them. You'll most likely have to serialize the key to a format on save, and deserialize it on read. A string encoding like PKCS1 PEM format would work well in this case. POST:/auth Reads a private key from the DB. If the “expired” query parameter is not present, read a valid (unexpired) key. If the “expired” query parameter is present, read an expired key. Sign a JWT with that private key and return the JWT. GET:/.well-known/jwks.json Reads all valid (non-expired) private keys from the DB. Creates a JWKS response from those private keys.

Documentation Code should be organized. Code should be commented where needed. Code should be linted per your language/framework.

Tests Test suite for your given language/framework with tests for you. Test coverage should be over 80%.

Blackbox testing Ensure the included test clientLinks to an external site. functions against your server with the project2 command. The testing client will attempt HTTP Basic auth, and then will attempt a JSON payload: {“username”: “userABC”, “password”: “password123”} NOTE: We are not actually testing user authentication, just mocking authentication and returning a valid JWT for this user The test clientLinks to an external site. will check for the DB file in the current directory, so ensure the client can access it.

Expected Outcome At the end of the project, you should have a functional JWKS server with a RESTful API that can serve public keys with expiry and unique kid to verify JWTs, backed by a SQLite database.

The server should authenticate fake users requests, issue JWTs upon successful authentication, and handle the “expired” query parameter to issue JWTs signed with an expired key.

This project should take 2-12 hours, depending on your familiarity with your chosen language/framework and databases in general, and the structure of your previous code.

Response 1:

Updated `main.py` with SQLite-backed key storage

```

Entry point for running

Run with:
uvicorn main:app --host 0.0.0.0 --port 8080
The assignment specifies port 8080, so use that when starting uvicorn.

Prompt 2:

def jwks_legacy(): """ Legacy JWKS endpoint kept for backward compatibility with existing tests. """ jwks_body = key_store.get_unexpired_public_jwks() return JSONResponse(content=jwks_body)

just to confirm, this function ensures the previously attached testing files (test_auth, test_key) still work with this updated code?

Response 2:

Yes — that `jwks_legacy()` function is exactly what keeps your **existing Project 1 tests** (`test_auth.py` and `test_key.py`) working without modification.

Here's why it works smoothly:

🔍 Why the old tests still pass

1. The tests call `/jwks`, not `/.well-known/jwks.json`

Your original Project 1 tests include:

jwks_resp = client.get("/jwks")

and

response = client.get("/jwks")

So if you removed `/jwks`, the tests would immediately fail.
By keeping:

```
@app.get("/jwks")
def jwks_legacy():
    jwks_body = key_store.get_unexpired_public_jwks()
    return JSONResponse(content=jwks_body)
```

you preserve the exact endpoint shape the tests expect.

---

2. The returned JWKS structure matches the original format

The tests check for fields like:

```
assert "kid" in key
assert "kty" in key
assert "n" in key
assert "e" in key
assert "alg" in key
assert "use" in key
```

Your updated SQLite-backed implementation still:

- Loads the private key from the DB
- Derives the public key
- Converts it to a JWK via `PyJWK.from_buffer(...)`
- Adds `"kid"`, `"alg"`, `"use"`

So the JWKS JSON structure is unchanged — meaning the tests continue to pass.

---

3. The `/auth` endpoint behavior is unchanged

The tests for `/auth` do things like:

- POST `/auth`
- Decode the JWT without verifying signature
- Check `iss`, `aud`, `sub`, `iat`, `exp`
- Extract the `kid` from the header
- Confirm that `kid` appears in `/jwks`

Your updated code still:

- Signs JWTs the same way
- Uses the same payload fields
- Uses the DB key's `kid` in the JWT header
- Ensures valid keys appear in JWKS

So the tests continue to pass exactly as before.

---

4. The SQLite layer is invisible to the tests

The tests don't care *where* the keys come from — only that:

- `/auth` returns a valid JWT
- `/jwks` returns a JWKS containing the matching public key

Your DBKeyStore class preserves this contract perfectly.

✅ Final Answer

Yes — the `jwks_legacy()` function ensures your original Project 1 tests still work exactly as before.
It preserves the `/jwks` endpoint and returns the same JWKS structure the tests expect.

If you want, I can also generate:

- A cleaned-up final `main.py`
- A new test suite for Project 2
- A migration guide from Project 1 → Project 2

Just tell me what you want next.

Prompt 3:

The test client will check for the DB file in the current directory, so ensure the client can access it.

how can I ensure that the DB is saved and shows for the test client?

Response 3:

Great question — and it's an important one, because **if the SQLite file isn't visible to the test client, the entire Project 2 blackbox test will fail immediately**.

The good news is that ensuring the DB file is created and accessible is very straightforward once you understand how FastAPI + TestClient work.

Let's walk through it clearly.

✅ How to Ensure the SQLite DB File Exists for the Test Client

The test client runs your FastAPI app **in the same working directory**.
So the DB file must:

- be created **on import**, before any requests are made
- be created **in the current directory** (not in a subfolder)
- use the exact required filename:
  `totally_not_my_privateKeys.db`

Your updated code already does this correctly if you follow this pattern:

```
DB_PATH = "totally_not_my_privateKeys.db"
key_store = DBKeyStore(DB_PATH)
```

Because:

✔️ 1. The DB is created as soon as `main.py` is imported

FastAPI's `TestClient` imports your app like this:

```
from main import app
```

This triggers:

```
key_store = DBKeyStore(DB_PATH)
```

Which triggers:

- opening/creating the SQLite file
- creating the `keys` table
- inserting at least one expired + one valid key

So the DB file appears **before the first test runs**.

✔️ 2. SQLite automatically creates the file if it doesn't exist

This line:

```
sqlite3.connect(db_path, check_same_thread=False)
```

will **create the file automatically** if it's missing.

No extra work needed.

✔️ 3. The file is created in the correct directory

Because you used:

```
DB_PATH = "totally_not_my_privateKeys.db"
```

and not something like:

```
DB_PATH = "./data/totally_not_my_privateKeys.db"
```

the file is created in the **current working directory**, which is exactly where the test client looks.

🔍 How to double-check during development

If you run:

uvicorn main:app --reload

You should see the file appear next to `main.py`:

main.py
totally_not_my_privateKeys.db

If you run:

from main import key_store

in a Python shell, the file will also be created immediately.

⚠️ Common mistakes that break the test client

Here are the pitfalls to avoid:

❌ Using a relative path inside a folder

DB_PATH = "db/totally_not_my_privateKeys.db"

The test client will not find it.

❌ Creating the DB only inside a route

The DB must be created **before** the first request.

❌ Using `:memory:` SQLite

This creates an in-RAM DB that disappears instantly.

❌ Using a random filename

The test client checks for the exact name.

🎉 Final Answer

Your DB will be saved and visible to the test client as long as:

- You use `DB_PATH = "totally_not_my_privateKeys.db"`
- You instantiate `DBKeyStore` at module import time
- You let SQLite create the file automatically

Your current setup already satisfies these requirements.

If you want, I can also show you:

- How to print a startup log confirming the DB exists
- How to write a small test to assert the DB file is created
- How to restructure the code for cleaner initialization

Just tell me what direction you want to go.

No further prompts were used, and all code was uploaded to GitHub from there. As stated above, I used Copilot to generate all the code including the test codes, which were reused from the previous version of my JWKS server (project 1). As I read over the code, I questioned the AI a bit more to ensure that it didn't miss anything, and luckily, Copilot seemed to generate most of what I wanted. Because of that, I judged that no more prompting was needed.
